

# Query Answering with Incomplete Information: Conjunctive Queries over Naive Tables

Formal Methods

Giuseppe De Giacomo

# Incomplete information and query answering

- Incomplete information in data: missing / unknown / partially specified data
- Query answering

- ▶ Over usual databases (complete information):  
QA by evaluation (or "model checking")

$$D \models Q$$

i.e.,  $D$  is seen as an interpretation (for simplicity we assume the query to be boolean, no free variables)

- ▶ Over incomplete databases (incomplete information):  
QA by logical implication (or "entailment")

$$\forall \mathcal{I}. \mathcal{I} \models D \text{ implies } \mathcal{I} \models Q$$

# Incomplete databases

A common form of incomplete databases are the so-called “naive tables”, which include values and “labelled nulls” (standing for **unknown values**) [IL84].

## Example

*Employee*

<i>name</i>
Smith
<i>null</i> <sub>1</sub>
Brown

*Manager*

<i>mgr</i>	<i>mgd</i>
Smith	<i>null</i> <sub>1</sub>
<i>null</i> <sub>1</sub>	Brown
Brown	<i>null</i> <sub>2</sub>

- **Const**: we have infinite constants, corresponding to domain objects as usual;
- **Nulls**: we have a countably infinite set of nulls, corresponding to variables ranging over *Cons*;
- **Tables are incomplete**, i.e., more tuples may belong to them, corresponding to the so called “open-world-assumption” or OWA. (For example *null*<sub>2</sub> belongs to *Employee* though not reported in the table.)

# Incomplete databases: semantics

Semantics of incomplete databases:

- A valuation function for nulls is a assignment function  $\sigma : \text{Nulls} \rightarrow \text{Const}$  (essentially **nulls** are considered as individual **variables** in logic).
- We denote by  $\mathcal{I}, \sigma \models D$  the fact that for every tuple  $(t_1, \dots, t_n) \in P$  for each table  $P$  we have  $\mathcal{I}, \sigma \models P(t_1, \dots, t_n)$ .
- We define in logic the set of databases completing  $D$  as

$$\text{Models}(D) = \{\mathcal{I} \mid \text{there exists a } \sigma \text{ such that } \mathcal{I}, \sigma \models D\}$$

## Example

<i>Employee</i>	<i>Manager</i>																												
<i>Employee</i>	<i>Manager</i>	<i>Employee</i>	<i>Manager</i>																										
<table border="1"><thead><tr><th><i>name</i></th></tr></thead><tbody><tr><td>Smith</td></tr><tr><td><i>null</i><sub>1</sub></td></tr><tr><td>Brown</td></tr></tbody></table>	<i>name</i>	Smith	<i>null</i> <sub>1</sub>	Brown	<table border="1"><thead><tr><th><i>mgr</i></th><th><i>mgd</i></th></tr></thead><tbody><tr><td>Smith</td><td><i>null</i><sub>1</sub></td></tr><tr><td><i>null</i><sub>1</sub></td><td>Brown</td></tr><tr><td>Brown</td><td><i>null</i><sub>2</sub></td></tr></tbody></table>	<i>mgr</i>	<i>mgd</i>	Smith	<i>null</i> <sub>1</sub>	<i>null</i> <sub>1</sub>	Brown	Brown	<i>null</i> <sub>2</sub>	<table border="1"><thead><tr><th><i>name</i></th></tr></thead><tbody><tr><td>Smith</td></tr><tr><td><i>null</i><sub>1</sub></td></tr><tr><td>Brown</td></tr></tbody></table>	<i>name</i>	Smith	<i>null</i> <sub>1</sub>	Brown	<table border="1"><thead><tr><th><i>mgr</i></th><th><i>mgd</i></th></tr></thead><tbody><tr><td>Smith</td><td><i>null</i><sub>1</sub></td></tr><tr><td><i>null</i><sub>1</sub></td><td>Brown</td></tr><tr><td>Brown</td><td><i>null</i><sub>2</sub></td></tr></tbody></table>	<i>mgr</i>	<i>mgd</i>	Smith	<i>null</i> <sub>1</sub>	<i>null</i> <sub>1</sub>	Brown	Brown	<i>null</i> <sub>2</sub>

## Certain answers to a query

An incomplete database acts like a logical theory: it selects models.

### Query answering in complete databases

The **answer** to a query  $q(\vec{x})$  over a complete database  $D$ , denoted  $q^D$ , is the set of tuples  $\vec{c}$  of constants of  $Const$  such that the  $\vec{c} \in q^D$  is true in  $D$ .

### Query answering in incomplete databases

The **certain answer** to a query  $q(\vec{x})$  over an incomplete database  $D$ , denoted  $cert(q, D)$ , is the set of tuples  $\vec{c}$  of constants of  $Const$  such that  $\vec{c} \in q^{\mathcal{I}}$ , for every model  $\mathcal{I}$  of  $D$ .

Note:

- If  $q$  is boolean, and  $D$  is incomplete: we write  $D \models q$  iff  $q$  evaluates to true in every model  $\mathcal{I}$  of  $D$ , (otherwise we write  $D \not\models q$ ).
- We use the same notation as for query answering based on evaluation: the difference is in the incompleteness of the database.

# Query languages for incomplete databases

Which query language to use?

① Full SQL (or equivalently, first-order logic)

- ▶ NO: in the presence of incomplete information, query answering becomes **undecidable** (FOL validity).  
(Notice this holds already for an empty incomplete database!)

② Conjunctive queries (or better union of conjunctive queries)

- ▶ Conjunctive queries are well behaved wrt containment. Can they be used for query answering in presence of incomplete information.  
**YES!** See what follows.

# Conjunctive queries and incomplete databases

A **conjunctive query (CQ)** is a first-order query of the form

$$q(\vec{x}) \leftarrow \exists \vec{y}. R_1(\vec{x}, \vec{y}) \wedge \dots \wedge R_k(\vec{x}, \vec{y})$$

where each  $R_i(\vec{x}, \vec{y})$  is an atom using (some of) the free variables  $\vec{x}$ , the existentially quantified variables  $\vec{y}$ , and possibly constants.

We will also use the simpler Datalog notation:

$$q(\vec{x}) \leftarrow R_1(\vec{x}, \vec{y}), \dots, R_k(\vec{x}, \vec{y})$$

*Note:*

- CQs contain no disjunction, no negation, no universal quantification.
- Correspond to SQL/relational algebra **select-project-join (SPJ) queries** – the most frequently asked queries.
- A Boolean CQ is a CQ without free variables  $\Rightarrow q() \leftarrow \exists \vec{y}. R_1(\vec{y}) \wedge \dots \wedge R_k(\vec{y})$ .

# Conjunctive queries and incomplete databases

Containment of conjunctive queries  $q_1 \subseteq q_2$  is decidable: and LOGSPACE in  $q_1$  and NP-complete in  $q_2$  [CM77].

Given an incomplete database  $D$  as above we can construct in linear time a (boolean) conjunctive query  $q_D$  that fully captures it.

- For each tuple in a table of  $D$  becomes an atom in the conjunctive query  $q_D$ .
- For each labelled nulls occurring in  $D$  becomes an existentially quantified variable in  $q_D$ .

## Example

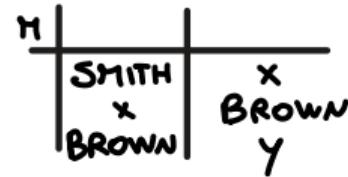

$E(\text{employee})$

name
Smith
null <sub>1</sub>
Brown

$M(\text{anager})$

mgr	mgd
Smith	null <sub>1</sub>
null <sub>1</sub>	Brown
Brown	null <sub>2</sub>

$$\exists x_1, x_2. E(\text{Smith}) \wedge E(x_1) \wedge E(\text{Brown}) \wedge M(\text{Smith}, x_1) \wedge M(x_1, \text{Brown}) \wedge M(\text{Brown}, x_2)$$

## Theorem ([IL84])

Let  $D$  be a database with incomplete information as above (naive tables),  $q_D$  the corresponding conjunctive query constructed as above, and  $q$  a boolean (union) of conjunctive query. Then:

$$D \models q \text{ iff } q_D \subseteq q$$

*Proof.*

- ① Observe that the models of  $D$  by construction coincide with that of the formula  $q_D$ : that is  $\forall \mathcal{I}. \mathcal{I} \models D \text{ iff } \mathcal{I} \models q_D$ .
- ② Moreover,  $q_D \subseteq q$  in the case of boolean queries stands for  $\forall \mathcal{I}. \mathcal{I} \models q_D$  implies  $\mathcal{I} \models q$ , or simply  $q_D \models q$ .
- ③ Hence, by (1)  $D \models q$  iff  $q_D \models q$ . □

# Conjunctive queries and incomplete databases

Using Chandra & Merlin Theorem [CM77], we get:

## Theorem ([IL84])

Let  $D$  be a database with incomplete information as above (naive tables),  $q_D$  the corresponding conjunctive query constructed as above,  $\mathcal{I}_{q_D}$  its canonical database, and  $q$  a boolean (union) of conjunctive query. Then:

$$D \models q \text{ iff } \mathcal{I}_{q_D} \models q$$

Note:  $\mathcal{I}_{q_D}$  is exactly  $D$  with nulls interpreted as additional constants!

Hence:

## Compute certain answers of non boolean CQs over incomplete databases

Given a non boolean (U)CQ  $q$  and an incomplete database  $D$ :

- ① Evaluate  $q$  over  $D$  as it was a complete database
- ② filter out all answers where null appears (certain answers are constituted by tuples of constants in  $Const$ )

## Conjunctive queries and incomplete databases

As a consequence of the above theorem we have:

Computing certain answers for (union) of conjunctive queries over databases with incomplete information (naive tables) is:

- **LOGSPACE** in data complexity
- **NP-complete** in query complexity and combined complexity

Note1: Exactly as for the case of complete information!

Note2: Use of CQs is crucial, since for full FOL we get undecidability!

## Examples of CQs over an incomplete database

### Example

$E(\text{mployee})$

<i>name</i>
Smith
<i>null</i> <sub>1</sub>
Brown

$M(\text{anager})$

<i>mgr</i>	<i>mgd</i>
Smith	<i>null</i> <sub>1</sub>
<i>null</i> <sub>1</sub>	Brown
Brown	<i>null</i> <sub>2</sub>

- **Queries:**  
 $q_1(x, y) \leftarrow M(x, y)$   
 $q_2(x) \leftarrow \exists y. M(x, y)$   
 $q_3(x) \leftarrow \exists y_1, y_2, y_3. M(x, y_1) \wedge M(y_1, y_2) \wedge M(y_2, y_3)$   
 $q_4(x, y_3) \leftarrow \exists y_1, y_2. M(x, y_1) \wedge M(y_1, y_2) \wedge M(y_2, y_3)$

- **Answers:**  
 $q_1: \{ \}$   
 $q_2: \{ \text{Smith}, \text{Brown} \}$   
 $q_3: \{ \text{Smith} \}$   
 $q_4: \{ \}$

# Conclusion

## Incomplete information

Several other forms of incomplete information have been studied in the literature of Databases and especially in the literature of **Knowledge Representation and Reasoning** in Artificial Intelligence.

These include:

- Knowledge Bases
- Ontologies, Description Logics, Semantic Technologies
- Reasoning about Actions (incomplete information also on the dynamics)
- ...

## Note

Only in very few cases dealing with incomplete information can be done through query evaluation techniques.

If interested, take the course on **Knowledge Representation and Semantic Technologies**.
